The appendix is one of the human organs that attracts little attention, hence termed an ineffectual blind tube. Nonetheless, this intestinal organ at the junction between the cecum and terminal ileum, undergoes pathological changes that have a significant influence on human health. This organ is also susceptible to conditions such as appendicitis and carcinoid tumors. The World Health Organization (WHO) classifies appendiceal tumors into epithelial, non-epithelial or secondary. Epithelial tumors include adenoma, carcinoma and carcinoid. On the other hand, non-epithelial tumors of mesenchymal origin include neuroma, lipoma, leiomyoma, gastrointestinal stromal tumor (GIST) and their malignant forms. Malignant lymphoma and Kaposi’s sarcoma are also possible appendiceal growths.

Acute abdominal pain is one of the most common earliest indicators of any clinical issues. The earliest known case of an appendiceal tumor dates back to 1882. Appendiceal tumors constitute 0.2% to 0.5% of all primary neoplasms seen in the gastrointestinal tract. This type of tumor is rare compared to other tumors that affect the gastrointestinal tract.

Acute abdominal pain is one of the most common earliest indicators of any clinical issues. The earliest known case of an appendiceal tumor dates back to 1882. Appendiceal tumors constitute 0.2% to 0.5% of all primary neoplasms seen in the gastrointestinal tract. This type of tumor is rare compared to other tumors that affect the gastrointestinal tract.

Appendiceal tumors could arise from any cell along its walls. Unfortunately, there is no solid understanding of their pathogenesis. In addition, patients with appendiceal tumors are mostly asymptomatic; in rare instances, acute appendicitis can be an early indicator of an abdominal mass. Typically, the anomaly is detected during an abdominal surgery such as appendectomy, often as a result of acute appendicitis. The growths could be detected by CT scans where they appear as abdominal masses.

The aim of this study is to determine the incidence rate of appendiceal tumors.

METHOD

All histopathological specimens of appendectomies from 1 January 2006 and 31 December 2015 were reviewed. Only cases which had complete clinical data and histological records were included in the study.

Two thousand three hundred ten pediatric and adult appendectomies were performed during the 10-year period.

The sample included negative appendectomies where the histological examination established that the appendix was normal. The following data were documented: age, gender, diagnosis, tumor size, location and metastasis.

The WHO classification of appendiceal tumors was used to classify the tumors into carcinoid, benign and malignant. Two cases of mucocele of the appendix and eight cases due to incomplete clinical data were excluded from the study.

The data was analyzed using SPSS 19.0 statistical package. The Chi-Square test was used to compare categorical data whereby a P-value of <0.05 was considered significant. The continuous data generated was expressed in the form of mean and standard deviation while descriptive analysis of frequencies and percentages featured as part of the statistical analysis.

RESULT

Two thousand three hundred ten appendix specimens were documented; 1,456 (63%) were male and 854 (37%) were female with a male to female ratio of 1.7:1.

One hundred eighty-four (8%) appendices were normal, 1,857 (80.4%) were inflamed appendices and 19 (0.82%) were appendiceal tumors, 250 (10.8%) were lymphoid hyperplasia, fibrosis and fecalith. Nine (0.38%) of the appendiceal tumors were carcinoid tumors, 6 (0.25%) were benign tumors, and 4 (0.17%) were malignant tumors, see table 1.

Six (0.25%) carcinoid tumors were associated with appendicitis, and one (0.04%) patient had a goblet cell carcinoid tumor which metastasized, see figure 1 (A and B). Additionally, nine (0.38%) of the tumors were located at the tip of the appendix, while six (0.25%) had invaded the submucosa. Four (0.17%) benign tumors were mucinous cystadenomas, and two (0.08%) were appendiceal neuromas, see table 1 and figure 2. Both cases of appendiceal neuroma were found to be associated with fibrous obliteration. There were no patients with carcinoid syndrome or signet ring carcinoma. Figures 3(A) and 3(B) show two cases of adenocarcinoma.

The mean age of the presentation of benign tumors was 38.8 years for both sexes; nonetheless, the average age for males is 33.5 years and 49.5 years for females.

**DISCUSSION**

In our study, the prevalence of appendiceal tumors was 0.82% compared to 0.7% in South Korea and Israel. In our study, the average age of presentation for malignant tumors was 46 years, which is lower than several studies where the mean age was 57-61 years. In our study, the average size of carcinoid tumors was 3.79 mm. A South Korean study reported an average size of 8.6 mm. An appendectomy is an appropriate treatment approach for carcinoid tumors less than 1 cm to 2 cm in size.

Carcinoid tumors in the appendix have a 2% to 4.7% chance of developing into malignancy and lower incidence of metastasis compared to other types of carcinoid growths that occur in the lungs, intestines, ovaries or kidneys. In our study, one of the nine carcinoid tumors (goblet cell) metastasized; it was an aggressive adenocarcinoid tumor with carcinoid features, similar to other studies. Other studies revealed that the mean age of presentation of goblet cell carcinoid ranges between 52 and 59 years. In our study, this type of tumor was diagnosed in a 51-year-old female.

A study by Roggo et al found that 78% of carcinoid tumors were located at the tip of the appendix; another study by Lee et al found it to be 66.7%. On the other hand, goblet cell carcinoids mostly occur in the middle-third of the appendix. In our study, the average size of carcinoid tumors was 3.79 mm. A South Korean study reported an average size of 8.6 mm. An appendectomy is an appropriate treatment approach for carcinoid tumors less than 1 cm to 2 cm in size.

Benign tumors are usually asymptomatic and account for about 0.2%. These abnormal masses are mostly found incidentally, similar to other appendiceal tumors. The most common type of benign tumor is mucinous cystadenoma. We found that mucinous cystadenomas occur in 0.2% of appendices compared to 0.4% to 0.6% in other studies. The treatment is total excision to avoid any malignant transformation and prevent pseudomyxoma peritonei. Based on the reviewed literature, the prevalence of mucocoele is 0.29% to 0.4%. A neurofibroma is another common benign tumor which is known to cause fibrous obliteration. This was evident in both cases in this study.

Adenocarcinoma is the most common primary malignancy of the appendix. According to Langlie-Lesnik, males are 2-3 times more likely to be diagnosed with this primary malignancy compared to females. Although this is a relatively rare type of malignant tumor of the appendix, it accounts for 4% to 6% of all appendiceal tumors.

Adenocarcinoma tends to perforate. One case of mucinous cystadenocarcinoma in our study had perforated. The mean age of presentation of adenocarcinoma in our study was 46 years.

Based on the findings of this study, more men than women were diagnosed with carcinoid tumors. A possible justification could be that there were almost twice as many men as women who underwent appendectomies during the studied period. One-third of the women reviewed were diagnosed with benign tumors, while malignant tumors of the appendix appeared more commonly among males. An appendectomy is the common form of treatment for an appendiceal tumor that measures less than 1 cm to 2 cm, where there are no signs of lymphovascular invasion.

**CONCLUSION**

Appendiceal tumors are rare; nonetheless, carcinoid tumors are the most common tumor in the appendix. Additionally,
mucinous cystadenoma is the most common benign tumor. Appendiceal tumors are slow-growing and are often detected before they grow large enough to metastasize. The most popular treatment approach is appendectomy. The data is not entirely reliable and cannot be used to present a solid conclusion regarding the relationship between appendiceal tumors, patients’ age and gender. Nevertheless, the data in this study can be used for comparison purposes in future studies.
