A1. Figure 1 is a lateral view through plain X-ray, and figure 2 is an anterior-posterior plain X-ray.

A2. Large amount of pneumoperitoneum in figure 1 and tennis ball sign in figure 2.

A3. Gastric perforation and bowel perforation.

**DISCUSSION**

Neonatal gastric perforation is a rare surgical emergency associated with high morbidity and mortality. It accounts for 7% of all neonatal gastrointestinal perforations. The etiology of this condition is unknown. Three theories were postulated: ischemia, trauma, and spontaneous perforation are acceptable mechanisms for gastric perforation in neonate1.

Neonatal gastric perforation can be classified into primary pathology, such as gastroschisis, tracheoesophageal fistula and duodenal obstruction. These pathologies could raise intragastric pressure leading to gastric perforation2.

The secondary pathology, such as bag-mask resuscitation, forceful nasogastric tube insertion, and positive pressure ventilation are the most common causes of neonatal gastric perforation. Sepsis, hypoxia, prematurity, and stress in the neonate are other causes which could explain the ischemic effect of gastric mucosa leading to gastric perforation3.

Spontaneous gastric perforation could be due to vomiting or incoordination in preterm infants. This condition is usually found in full-term newborns, but could also be found in low-birth weight, hypoxic and premature infants3.

Gastric and intestinal perforation in preterm is commonly due to necrotizing enterocolitis3.

The clinical features of gastric perforation in neonates include lethargy, vomiting, abdominal distension and respiratory distress. Abdominal distension was the most common clinical findings reported in 71% of patients. The respiratory distress was reported in 50% of patients; the distress depends on the severity of abdominal distension. Pneumoperitoneum is one of the prominent findings in plain x-rays in cases of neonatal gastric perforation4.

The incidence of neonatal gastric perforation is 1 in 5000 live births. Neonatal gastric perforation is higher in male than female and more common in black than white4.

The main management is surgical intervention after resuscitation. The prognosis of this condition depends on early diagnosis, resuscitation and early surgical intervention4. High mortality risk factors are associated with hypoxia, duration of illness and maturity degree4,5,6.
